Crystal structure and Hirshfeld surface analysis of 2-methylquinazolin-4(3H)-one hydrochloride

Proof instructions

Proof corrections should be returned by **16 January 2025**. After this period, the Editors reserve the right to publish your article with only the Managing Editor's corrections.

Please

- (1) Read these proofs and assess whether any corrections are necessary.
- (2) Check that any technical editing queries highlighted in **bold underlined** text have been answered.
- (3) Send corrections by email to checkin@iucr.org. Please describe corrections using plain text, where possible, giving the line numbers indicated in the proof. Please do not make corrections to the pdf file electronically and please do not return the pdf file. If no corrections are required please let us know.

Please check the following details for your article:

The title salt, $C_9H_9N_2O^+Cl^-$, has orthorhombic (*Pbcm*) symmetry. Except for two methyl H atoms, all atoms of the molecular cation are located about a mirror plane, making the quinazolinium moiety exactly planar. Individual molecules are arranged in (001) layers in the crystal. Supramolecular features include $N-H \cdots Cl$ hydrogen-bonding interactions, leading to zigzag chains along [010] with $D_1^1(2)$ and $C_1^2(6)$ graph-set motifs. Additionally, weak $\pi-\pi$ stacking interactions occur between benzene rings in adjacent layers. Hirshfeld surface analysis revealed that the most important contributions to the surface contacts are from $H \cdots H$ (36.1%), $H \cdots C/C \cdots H$ (25.8%), and $H \cdots O/O \cdots H$ (17.7%) interactions.

1. Chemical context

Syntheses based on pyrimidines (quinazolines) condensed with a benzene ring are widely used in agricultural and medical practice (Zayed, 2023). In particular, drugs based on compounds of this class are used against viruses, microbes, colds and cancer (Guangdi *et al.*, 2021; Arachchige & Yi, 2019) as well as stimulants and pesticides (Alsibae *et al.*, 2023). Examples of such types of drugs that have been used successfully against various types of cancer in recent years are *imatinib*, *erlotinib*, *lapatinib* and *afatinib*. Therefore, targeted syntheses of biologically active compounds containing this pharmacophore (*i.e.* the quinazoline ring), are important to determine their physical, chemical and biological properties. In this context, we report here the molecular and crystal structures of 2-methyl quinazolin-4(3H)-one hydrochloride (**I**) and its Hirshfeld surface analysis.

2. Structural commentary

The asymmetric unit of (**I**) consists of a quinazolinium cation and a Cl^- anion (Fig. 1). Except for methyl H atom H11b and

Table 1

Hydrogen-bond geometry (Å, °).

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
$N1-H1\cdots Cl1$	0.86	2.19	3.052 (2)	176
$N3-H3\cdots Cl1^i$	0.86	2.25	3.108 (3)	175

Symmetry code: (i) $-x, -y, z + \frac{1}{2}$.

its symmetry-related counterpart, all atoms are located on a mirror plane, making the benzene and pyrimidine rings in the cation exactly planar (Fig. 2). The basic heteroatom N1 of the pyrimidine ring is protonated, and the resulting positive charge is delocalized within the $-N-C-N-$ moiety in the ring, making the $C2-N1$ and $C2-N3$ bonds shorter than the $C4-N3$ and $C9-N1$ bonds. Similar differences were observed in related compounds reported in the literature (Sharma *et al.*, 1993; Turgunov *et al.*, 2003; Tozhiboev *et al.*, 2005, Tojiboev *et al.*, 2021).

3. Supramolecular features

In the crystal of (**I**), the cationic molecules are arranged in flat (001) layers. Individual molecules are linked to Cl^- anions through $N-H\cdots Cl$ hydrogen-bonding interactions (Table 1) into zigzag chains extending parallel to [010] (Fig. 3), generating $D_1^1(2)$ and $C_2^1(6)$ graph-set motifs (Bernstein *et al.*, 1995). In addition, weak highly slipped $\pi-\pi$ stacking interactions (Fig. 2) occur between benzene (centroid $Cg2$) rings in adjacent layers and involve contact distances $Cg2\cdots Cg2(1 - x, 1 - y, 1 - z)$ of 4.6592 (14) Å (slippage 3.280 Å).

Figure 1

The asymmetric unit of (**I**) with displacement ellipsoids drawn at the 50% probability level. The dotted turquoise line represents an $N-H\cdots Cl$ hydrogen bond.

Figure 2

Packing of (**I**) (a) along the a axis and (b) along the b axis, showing the $\pi-\pi$ interactions. Centroid-centroid distance is incorrect

Figure 3

Packing of (**I**) along the c axis. Hydrogen bonding between $N1-H1\cdots Cl$ and $N3-H3\cdots Cl$ is shown as blue dotted lines.

4. Hirshfeld surface analysis

A Hirshfeld surface analysis (Hirshfeld, 1977) was carried out using *CrystalExplorer* (Spackman *et al.*, 2021) to visualize non-covalent interactions in the crystal packing of (**I**). The Hirshfeld surface mapped over d_{norm} is represented in Fig. 4. The white surface indicates contacts with distances equal to the sum of van der Waals radii, and the red and blue colours indicate distances shorter or longer than the van der Waals

Figure 4

Three-dimensional Hirshfeld surface of (**I**) mapped over d_{norm} .

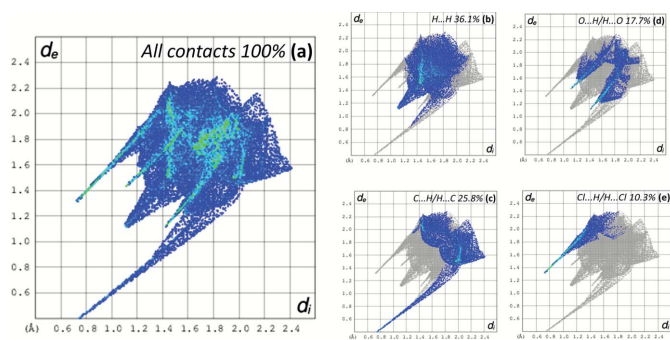

Figure 5
Two-dimensional fingerprint plots for the title compound, showing (a) all interactions, and decomposed into (b) H...H, (c) C...H/H...C, (d) O...H/H...O, (e) Cl...H/H...Cl interactions. Values for d_i and d_e represent the closest internal and external distances (in Å) from given points on the Hirshfeld surface.

radii, respectively. The bright-red spot near N1 indicates its role as a hydrogen-bond donor towards Cl1.

The most important contributions to the Hirshfeld surface arise from H...H contacts at 36.1% (Fig. 5b). C...H/H...C and O...H/H...O interactions follow with contributions of 25.8% and 17.7%, respectively (Fig. 5c,d). The classical N—H...Cl hydrogen bonds correspond to H...Cl/Cl...H contacts (10.3% contribution) and show up as a spike (Fig. 5e). Minor contributors are due to C...Cl/Cl...C (3.3%), N...H/H...N (2.4%), N...Cl/Cl...N (2.2%) and C...C (1.8%) interactions.

5. Database survey

A search of the Cambridge Structural Database (CSD, Version 5.43, last update November 2022; Groom *et al.*, 2016) for the 2-methylquinazolin-4(3H)-one moiety resulted in twelve hits with a similar planar conformation: ACANLC10 (Etter *et al.*, 1983), AWIYIR (Kalogirou *et al.*, 2021a), BIHJUA and BIHKAH (Liao *et al.*, 2018), BOLGAK (Etter *et al.*, 1983) and BOYMAD (Chadwick & Easton, 1983), DILFEL (Rybarczyk-Pirek *et al.*, 2013), RUGTEV (Kalogirou *et al.*, 2020), UQOGAL (Kalogirou *et al.*, 2021b) and YILLEM (Moghimi *et al.*, 2013). The main difference with respect to the molecular structures of these compounds is that the C2—N1 bond in the pyrimidine ring of (**I**) is slightly longer due to the protonation of the N atom.

6. Synthesis and crystallization

30 g (0.2 mol) of *N*-acetylanthranilic acid and 76.53 g (1.4 mol) of ammonium chloride were placed in a 250 ml round-bottom flask. The mixture was heated in a sand bath at 498–503 K for 4 h. Then the reaction mixture was cooled and treated with boiling water. The mixture was filtered and brought to pH 7–9, and then was left at room temperature. The precipitate was filtered off, washed with distilled water and dried. Recrystallization from ethanol yielded 20.4 g (76%) of 2-methylquinazolin-4(3H)-one; m.p. 511–513 K, $R_f = 0.28$. In order to

get 2-methylquinazolin-4(3H)-one hydrochloride crystals, the latter was dissolved in a mixture of ethanol and methanol (9:1 v:v) to which 10 drops of 30%_{w/v} HCl solution were added and stirred on a magnetic stirrer for 2 h. Crystal growth was carried out in a drying oven at 303 K. Colourless single crystals suitable for X-ray diffraction analysis were obtained after 5 d.

7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms were positioned geometrically (aromatic C—H = 0.93 Å, N—H = 0.86 Å and methyl C—H = 0.96 Å) and treated as riding atoms, with $U_{iso}(H) = 1.2U_{eq}(\text{aromatic C, N})$ or $1.5U_{eq}(\text{methyl C})$.
